Homework 12

Ryan Branagan

April 17, 2019

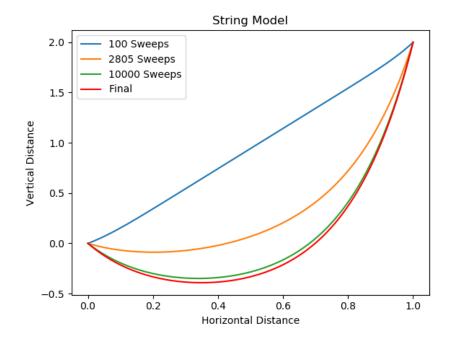

I probably shouldn't have but I combined Problems 1, 2, and 3 (Boundary Value Problems) into one file. I also did this with the PDE homework. The problems all built on each other and I also accidentally did Problem 2 when attempting Problem 1. To me using a while loop made much more sense than a for loop.

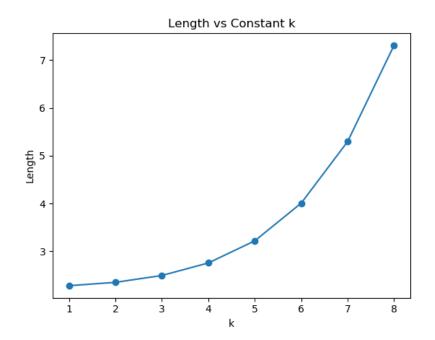

Problems 1,2, and 3

```
#Ryan Branagan
#Collaborators: N/A
#Branagan_hw12_p1_p2_p3.py
#4/11/19
import numpy as np
import pylab as p
#%%
#Parameters
k = 5.
xa = 0
xb = 1
ya = 0
yb = 2
N = 100
#Define things
xs = np.linspace(xa,xb,N)
ys = 2.*xs
h = xs[1]-xs[0]
#%%
#Problem 1
for i in range(10**6):
    ys[1:-1] = 0.5*(ys[:-2]+ys[2:])-(((k*(h**2))/2)*np.sqrt(1+(((ys[:-2]-ys[2:])**2)/((2s(h**2))/2))))
```

```
#%%
```

```
#Setup of Plotting
fig,ax = p.subplots(1,1)
#Sweeping
ys = 2.*xs
Sweeps = 0
while True:
   i = np.copy(ys)
   ys[1:-1] = 0.5*(ys[:-2]+ys[2:])-(((k*(h**2))/2)*np.sqrt(1+(((ys[:-2]-ys[2:])**2)/((2s(h**2))/2))))
   Sweeps = Sweeps + 1
    if Sweeps == 10**2 or Sweeps == (2.805*(10**3)) or Sweeps == 10**4:
       ax.plot(xs,ys,label=str(Sweeps)+" Sweeps")
    if np.mean(np.abs(ys-i)) < 10**-8:</pre>
       break
#Plotting
ax.plot(xs,ys,'r-',label="Final")
ax.set_title('String Model')
ax.set_xlabel('Horizontal Distance')
ax.set_ylabel('Vertical Distance')
ax.legend()
#%%
#Problem 3
def Length(x,y):
   return np.sqrt(1+(((y[1:]-y[:-1])/(x[1:]-x[:-1]))**2))
ks = np.linspace(1,8,8)
ans = np.zeros_like(ks)
for i,k in enumerate(ks):
   for j in range(Sweeps):
       L = Length(xs,ys)
   L[0] = L[0]*(3/2)
   L[-1] = L[-1]*(3/2)
    ans[i] = h*np.sum(L)
fig2,ax2 = p.subplots(1,1)
ax2.plot(ks,ans,'-o')
ax2.set_title('Length vs Constant k')
ax2.set_xlabel('k')
ax2.set_ylabel('Length')
```

For Problem 1, it takes greater than 10^4 sweeps to get close to the correct answer. At thirty thousand sweeps it looks the exact same as if you increase the number of sweeps.

For Problem 2, I set the loop to break when there was a difference of 10^{-8} resulting in about thirty thousand sweeps.

For Problem 3, I used the open integration and approximated the slope with the slope formula.

Problems 4 and 5

```
#Ryan Branagan
#Collaborators: Jack Featherstone
#Branagan_hw12_p4_p5.py
#4/17/19
import numpy as np
import pylab as p
#%%
#Defining Important Values
xa = -5.
xb = 5.

dx = (xb-xa)/N
dt = 0.25*dx/c
xs = np.linspace(xa,xb,J+1)
t0 = 0
tf = N*dt
ts = np.linspace(t0,tf,N+1)
y = np.zeros([J+1,N+1])
v = np.zeros([J+1,N+1])
A = 0.1
sigma = 1.
#Setting Initial Conditions
y[:,0] = A * np.exp(-xs**2/sigma**2)
y[:,1] = A * np.exp(-xs**2/sigma**2)
#%%
#These are for the Initial Conditions for 19.2/12.5
v[:,0] = ((2*A*c*xs)/(sigma**2))*np.exp(-(xs**2)/(sigma**2))
v[:,1] = ((2*A*c*xs)/(sigma**2))*np.exp(-(xs**2)/(sigma**2))
#%%
#Applying Method
```
